

ECO2100 Part 2 Homework 1

Derek Caughy

November 13, 2025

a)

Social welfare is given by:

$$S = f(k)(1 - u) - vk$$

Production of firm in match \downarrow
 Number of matches \downarrow
 total cost of vacancies \uparrow

Note that we want to solve the steady state level of unemployment. First note that

$$\frac{\text{change in unemployment across time, } =0 \text{ in steady state}}{\dot{u} = \delta(1 - u) - \frac{m(\lambda)}{\lambda}u}$$

matching rate of unemployed workers times unemployed
 rate of job destruction times employed

Thus in steady state:

$$0 = \delta - (\delta + \frac{m(\lambda)}{\lambda})u$$

$$\iff u = \frac{\delta}{\delta + \frac{m(\lambda)}{\lambda}} = \frac{\lambda\delta}{\lambda\delta + m(\lambda)}$$

Furthermore, note that

$$\lambda = \frac{u}{v} \iff v = \frac{u}{\lambda} = \frac{\delta}{\lambda\delta + m(\lambda)}$$

Thus we can write the social planner's problem

$$\max_{\lambda \geq 0, k > 0} f(k) \frac{m(\lambda)}{\lambda\delta + m(\lambda)} - k \frac{\delta}{\lambda\delta + m(\lambda)}$$

The Lagrangian can be written as:

$$\mathcal{L}(\lambda, k, \mu_1, \mu_2) = \frac{f(k)m(\lambda) - k\delta}{\lambda\delta + m(\lambda)} + \mu_1(k - \epsilon) + \mu_2\lambda$$

where $\epsilon > 0$ is an arbitrary constant.

b)

First note, that ϵ is arbitrary, therefore we can always choose some ϵ such that $k > \epsilon > 0$, thus by complementary slackness $\mu_1 = 0$. Secondly, for finite The first order conditions are written as follows:

$$\frac{f'(k)m(\lambda) - \delta}{\lambda\delta + m(\lambda)} = 0 \quad (\text{k})$$

$$\frac{f(k)m'(\lambda)(\lambda\delta + m(\lambda)) - (\delta + m'(\lambda))(f(k)m(\lambda) - k\delta)}{(\lambda\delta + m(\lambda))^2} + \mu_2 = 0 \quad (\lambda)$$

Inspecting condition (k) and taking the limit as $\lambda \rightarrow 0$ reveals that $\lambda \neq 0$. That is,

$$\lim_{\lambda \rightarrow 0} \frac{f'(k)m(\lambda) - \delta}{\lambda\delta + m(\lambda)} = \frac{-\delta}{\infty} < 0$$

By complementary slackness, it follows that $\mu_2 = 0$ Now inspect FOC (λ) we can derive:

$$f(k)m'(\lambda)(\lambda\delta + m(\lambda)) - (\delta + m'(\lambda))(f(k)m(\lambda) - k\delta) = 0$$

by the denominator necessairily being nonzero. This can be simplified:

$$\begin{aligned} & \lambda f(k)m'(\lambda) - f(k)m(\lambda) + k(\delta + m'(\lambda)) = 0 \\ \iff & (\lambda m'(\lambda) - m(\lambda))f(k) + k(\delta + m'(\lambda)) = 0 \\ \iff & \left(1 - \frac{\lambda m'(\lambda)}{m(\lambda)}\right)f(k) - k\left(\frac{\delta}{m(\lambda)} + \frac{m'(\lambda)}{m(\lambda)}\right) = 0 \end{aligned}$$

Define

$$\eta(\lambda) = \frac{\lambda m'(\lambda)}{m(\lambda)} \iff \frac{m'(\lambda)}{m(\lambda)} = \frac{\eta(\lambda)}{\lambda}$$

Then re-write the above:

$$\left(1 - \eta(\lambda)\right)f(k) - k\left(\frac{\delta}{m(\lambda)} + \frac{\eta(\lambda)}{\lambda}\right) = 0$$

c)

$$rJ(k) = f(k) - w - \delta(J(k) - V(k)) \quad (\text{i})$$

$$rV(k) = -k + m(\lambda)(J(k) - V(k)) \quad (\text{ii})$$

$$rW(k) = w - \delta(W(k) - U(k)) \quad (\text{iii})$$

$$rU(k) = \frac{m(\lambda)}{\lambda}(W(k) - U(k)) \quad (\text{iv})$$

d)

First, note that by $k = \bar{k}$ that the above Bellman equations are no longer functions of k . Furthermore, the equilibrium wage rate will be given by Nash Bargaining. That is

$$\begin{aligned} w &= \arg \max_{\beta} (W - U)^{\beta} (J - V)^{(1-\beta)} \\ &= \arg \max_{\beta} \beta \ln(W - U) + (1 - \beta) \ln(J - V) \end{aligned}$$

The first order condition yields:

$$\beta \frac{\frac{\partial W}{\partial w}}{W - U} + (1 - \beta) \frac{\frac{\partial J}{\partial w}}{J - V} = 0$$

The partial derivatives come from the fact that W and J are functions of w , while V and U are not. Re-writing iii:

$$W = \frac{w + \delta U}{r + \delta}$$

Doing the same for J in terms of i yields:

$$J = \frac{f(k) - w + \delta V}{r + \delta}$$

It becomes obvious that $\frac{\partial W}{\partial w} = -\frac{\partial J}{\partial w}$ thus the first order condition can be re-written:

$$\beta \frac{1}{W - U} - (1 - \beta) \frac{1}{J - V} = 0$$

$$\iff \beta(J - V) = (1 - \beta)(W - U)$$

Now we note the free entry condition which means that $V = 0$ we can re-write the FOC to be:

$$\begin{aligned} W - U &= \beta(W - U + J) \\ &\quad \uparrow \qquad \qquad \uparrow \\ &= \frac{w - rU}{r + \delta} \text{ from iii} \qquad \qquad = \frac{f(k) - w}{r + \delta} \text{ from i} \\ \iff \frac{w - rU}{r + \delta} &= \frac{\beta}{r + \delta}(f(k) - rU) \\ \iff w &= (1 - \beta)rU + \beta f(k) \end{aligned} \tag{garbage}$$

From the FOC we can also derive:

$$W - U = \frac{\beta}{1 - \beta} J$$

From ii we can obtain

$$J = \frac{k}{m(\lambda)}$$

Thus:

$$W - U = \frac{\beta}{1 - \beta} \frac{k}{m(\lambda)}$$

Which can be substituted into iv to obtain

$$rU = \frac{m(\lambda)}{\lambda} \frac{\beta}{1 - \beta} \frac{k}{m(\lambda)} = \frac{\beta}{1 - \beta} \frac{k}{\lambda}$$

Substituting into garbage and doing some simplifying:

$$\begin{aligned} w &= \beta \frac{k}{\lambda} + \beta f(k) \\ \iff w &= \beta(f(k) + \frac{k}{\lambda}) \end{aligned}$$

Now inspect ii using J from i

$$\begin{aligned} 0 &= -k + m(\lambda) \frac{f(k) - w}{r + \delta} \\ \iff w &= f(k) - \frac{r + \delta}{m(\lambda)} k \end{aligned}$$

Thus

$$\begin{aligned}\beta(f(k) + \frac{k}{\lambda}) &= f(k) - \frac{r + \delta}{m(\lambda)}k \\ \iff (1 - \beta)f(k) - k\left(\frac{\beta}{\lambda} + \frac{r + \delta}{m(\lambda)}\right) &= 0\end{aligned}$$

Setting $r = 0$ and solving for $f(k)$:

$$f(k) = \frac{1}{1 - \beta}k\left(\frac{\beta}{\lambda} + \frac{\delta}{m(\lambda)}\right)$$

Now taking the First order condition for λ and solving for $f(k)$:

$$f(k) = \frac{1}{1 - \eta(\lambda)}k\left(\frac{\delta}{m(\lambda)} + \frac{\eta(\lambda)}{\lambda}\right)$$

Then if the two solutions are equal we have

$$\begin{aligned}\frac{1}{1 - \eta(\lambda)}\left(\frac{\delta}{m(\lambda)} + \frac{\eta(\lambda)}{\lambda}\right) &= \frac{1}{1 - \beta}k\left(\frac{\beta}{\lambda} + \frac{\delta}{m(\lambda)}\right) \\ \iff (1 - \beta)\frac{\delta\lambda + \eta(\lambda)m(\lambda)}{\lambda m(\lambda)} &= (1 - \eta(\lambda))\frac{\delta\lambda + \beta m(\lambda)}{\lambda m(\lambda)} \\ \iff \beta &= \eta(\lambda)\end{aligned}$$

This is the same Hosios condition that we saw in class. The intuition is that the efficient solution depends on the elasticity of the matching function. In words, the bargaining power of the firm must be equal to the elasticity of the matching function for the firm.

e)

The second equilibrium condition for this economy, given that firms are allowed to choose k , would be that firms are optimally choosing k . Assume that \bar{k} from the previous question is optimal. Then in equilibrium (letting $r = 0$), it follows that

$$f(k) = \frac{1}{1 - \beta}k\left(\frac{\beta}{\lambda} + \frac{\delta}{m(\lambda)}\right)$$

Taking the derivative with respect to k

$$f'(k) = \frac{1}{1 - \beta}\left(\frac{\beta}{\lambda} + \frac{\delta}{m(\lambda)}\right)$$

Recall one of the first order conditions from b) that determined k^* and λ^* , and solve for $f'(k)$:

$$f'(k) = \frac{\delta}{m(\lambda)}$$

It follows that the market equilibrium and planner's solution will only have the same level of k if $\beta = 0$. This corresponds to the firms extracting all surplus of production. My best guess at the intuition would be that if firms are required to split surplus with the workers, they will underproduce compared to the efficient level of production. That is, the social planner simply maximized production subject to market frictions, while firms will maximize production minus wages subject to market frictions. The introduction of non-zero wages deters firms from entry. Figure 1 attempts to visualize this. The basic condition for firm profit maximization is expected marginal revenue, captured by $f'(k)$ is equal to expected marginal cost, captured by $w + k$. In the social planner's problem this marginal costs is simply k . This is obviously abstracting from the fact that firms only face costs of production in terms of k when not producing, but hopefully the intuition still holds. Even though firms do not face capital costs when operating, firms still maximize their expected value which includes expectations over when firms have vacancies.

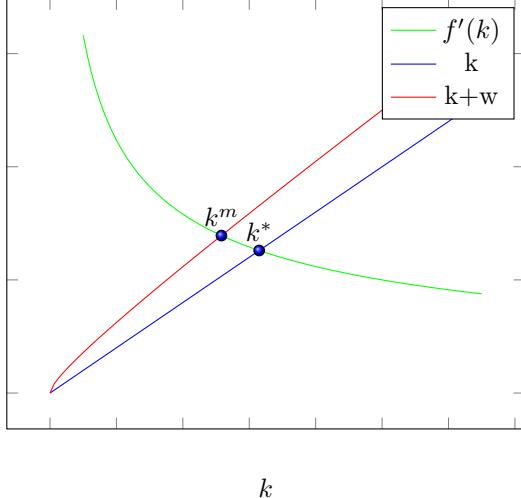

Figure 1: A really trash graph

f)

From the two efficiency conditions derived from parts d) and e) together imply that this economy will never be efficient. The two conditions on β are disjoint. Recall that the two joint conditions imply

$$0 = \beta = \eta(\lambda) = \frac{\lambda m'(\lambda)}{m(\lambda)} \neq 0$$

Equilibrium λ will only ever be efficient for a strictly positive bargaining power for workers, while the condition for k states that production will only ever be efficient when workers have no bargaining power. The incentives for the optimal queue length and the optimal level of production do not align. The two choices being made in the market economy are over capital and entry, while in the planner's economy the choices are for capital and queue length. The incentives for the firm do not take into account the value lost from the worker associated with a large queue length. A large queue length incentivises firms to enter by ensuring that costs of vacancies are small. Furthermore, firms, being the agent that decide capital in the market will only choose the efficient level when they are the sole beneficiaries of production. These in turn cause the market level of entry and capital to both be too small.
